

THE PROBLEM

Dental imaging assistants often jump straight to interpretation. A technically poor radiograph can produce confident-sounding but unreliable downstream guidance.

THE SOLUTION

Radiograph Ready is a research prototype that makes image quality a first-class step. It turns a small expert-scored pilot into a transparent learning experience: coverage, positioning, exposure, motion, and overall interpretability are reviewed before diagnosis.

WHAT THE PROTOTYPE SHOWS

The site combines pilot context, model comparison findings, a five-factor readiness triage interaction, and a de-identified contribution handoff. The score is deliberately illustrative so users can understand the rubric without mistaking it for a clinical prediction.

WHO BENEFITS

Students learn why calibration matters. Researchers get a clear benchmark frame for collecting harder cases. Dental teams get a safer product pattern: check whether the input is usable before asking an AI system to reason about it.

HEALTH IMPACT AND RIGOR

The project does not diagnose disease, rank treatment, or accept patient files. It uses explicit safety language, asks contributors to de-identify data, and keeps the contribution flow as a front-end email handoff until a secure endpoint is approved.
